What is network meta-analysis?

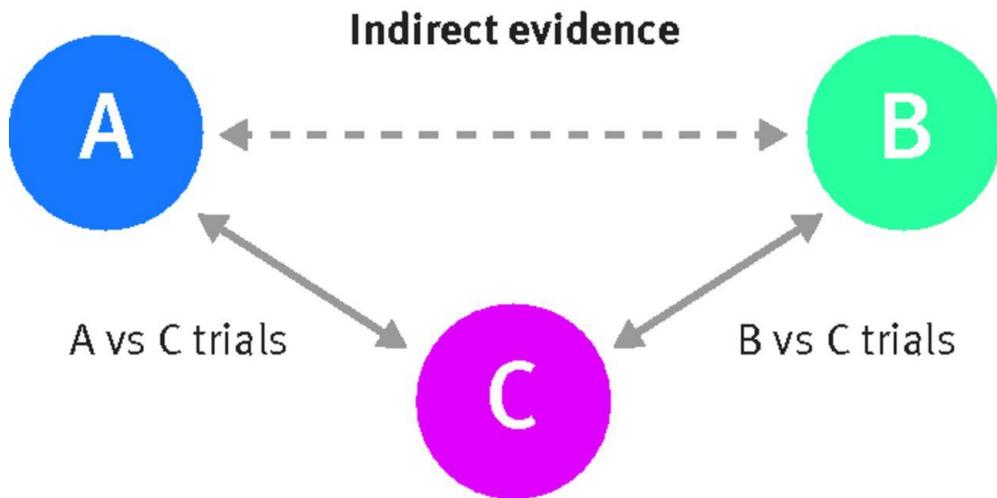

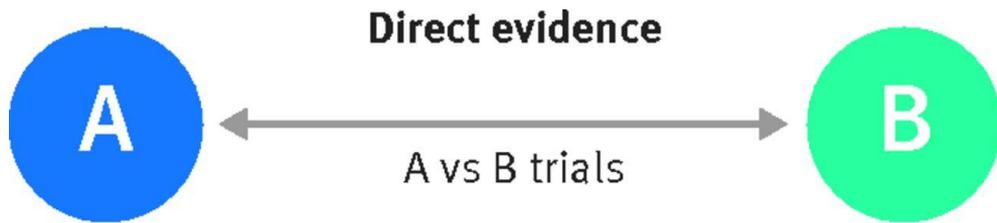

Network meta-analysis (NMA), termed multiple treatment meta-analysis or mixed treatment comparisons (MTC), was developed as an **extension** of pairwise meta-analysis to allow **comparisons of more than two interventions** in a single, coherent analysis of all the relevant RCTs.

Main advantages:

consistent and precise estimates of the relative effects of all interventions compared with every other in a single analysis using **both direct and indirect evidence**.

Network Meta-Analysis
for **Decision-Making**

ABSTRACT OBJECTIVE

To describe the comparative efficacy of drug and non-drug interventions for reducing symptoms of depression in people with dementia who experience depression as a neuropsychiatric symptom of dementia or have a diagnosis of a major depressive disorder.

DESIGN

Systematic review and meta-analysis.

data posed the greatest risk to review findings. In the network meta-analysis of studies including people with dementia without a diagnosis of a major depressive disorder who were experiencing symptoms of depression (213 studies; 25 177 people with dementia; between study variance 0.23), seven interventions were associated with a greater reduction in symptoms of depression compared with usual care: cognitive stimulation (mean difference -2.93, 95% credible interval -4.35 to -1.52), cognitive stimulation combined with a cholinesterase inhibitor
